

# TPS54318 2.95V 至 6V 输入、3A 输出、2MHz、同步降压 SWIFT™ 转换器

## 1 特性

- 两个可在 3A 负载下获得高效率的 30mΩ (典型值) MOSFET
- 开关频率: 200kHz 至 2MHz
- 整个温度范围内的电压基准: 0.8V ± 1%
- 同步至外部时钟
- 可调软启动/定序
- 欠压 (UV) 和过压 (OV) 电源正常输出
- 低运行和关断静态电流
- 安全启动至预偏置输出电压
- 逐周期电流限制、过热和频率折返保护
- 工作结温范围: -40°C 至 150°C
- 耐热增强型 3mm x 3mm 16 引脚超薄型四方扁平无引线 (WQFN) 封装
- 使用 TPS54318 并借助 WEBENCH® 电源设计器创建定制设计方案

## 2 应用

- 低压、高密度电源系统
- 针对高性能 DSP、FPGA、ASIC 和微处理器的负载点调节
- 宽带、网络互联及光纤通信基础设施

## 3 说明

TPS54318 器件一款全功能 6V、3A 同步降压电流模式转换器，具有两个集成的 MOSFET。

TPS54318 器件集成了 MOSFET、通过实施电流模式控制来减少外部组件数量、通过启用高达 2MHz 的开关频率来减小电感尺寸，并借助小型 3mm x 3mm 热增强型 QFN 封装尽量减小器件封装尺寸，从而实现小型设计。

TPS54318 器件可在整个温度范围内为多种负载提供电压基准 ( $V_{REF}$ ) 精度达 ±1% 的精确调节。

通过集成型 30mΩ MOSFET 和典型值为 350µA 的电源电流可使效率得到最大限度提升。通过使用 EN 引脚进入关断模式，关断电源电流可减少至 2µA。

欠压闭锁在内部设定为 2.6V，但可通过使能引脚上的电阻网络设定阈值将之提高。输出电压启动斜坡由软启动引脚控制。一个开漏电源正常信号表示输出处于其标称电压值的 93% 至 107% 之内。频率折返和热关断功能在过流情况下保护器件不受损坏。

## 5 Pin Configuration and Functions

### Pin Functions

PIN		I/O <sup>(1)</sup>	DESCRIPTION
NAME	NO.		
AGND	5	G	Analog ground should be electrically connected to GND close to the device.
BOOT	13	I	A bootstrap capacitor is required between BOOT and PH. If the voltage on this capacitor is below the minimum required by the BOOT UVLO, the output is forced to switch off until the capacitor is refreshed.
COMP	7	O	Error amplifier output, and input to the output switch current comparator. Connect frequency compensation components to this pin.
EN	15	I	Enable pin, internal pull-up current source. Pull below 1.2 V to disable. Float to enable. Can be used to set the on/off threshold (adjust UVLO) with two additional resistors.
GND	3 4	G	Power ground. This pin should be electrically connected directly to the power pad under the device.
PH	10 11 12		The source of the internal high-side power MOSFET, and drain of the internal low-side (synchronous) rectifier MOSFET.
PWRGD	14	O	An open drain output, asserts low if output voltage is low due to thermal shutdown, overcurrent, over/under-voltage or EN shut down.
RT/CLK	8	I/O	Resistor Timing or External Clock input pin.
SS	9	I/O	Slow-start. An external capacitor connected to this pin sets the output voltage rise time. Soft
VIN	1 2 16	I	Input supply voltage, 2.95 V to 6 V.
VSENSE	6		
Thermal Pad		G	GND pin should be connected to the exposed power pad for proper operation. This power pad should be connected to any internal PCB ground plane using multiple vias for good thermal performance.

(1) I = Input, O = Output, G = Ground

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) <sup>(1)</sup>

		MIN	MAX	UNIT
Input voltage	EN, PWRGD, VIN	-0.3	7	V
	RT/CLK	-0.3	6	
	COMP, SS, VSENSE	-0.3	3	
	BOOT		V <sub>PH</sub> + 8 V	
Output voltage	BOOT-PH		8	V
	PH	-0.6	7	
	PH (10 ns transient)	-2	7	
Source current	EN, RT/CLK		100	µA
Sink current	COMP, SS		100	µA
	PWRGD		10	mA
Operating junction temperature, T <sub>J</sub>		-40	150	°C
Storage temperature, T <sub>stg</sub>		-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### 6.2 ESD Ratings

		VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	±2000 V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins <sup>(2)</sup>	±500 V

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V <sub>VIN</sub>	Input voltage	3	6	V
T <sub>J</sub>	Operating junction temperature	-40	150	°C

### 6.4 Thermal Information<sup>(1)</sup>

	THERMAL METRIC <sup>(2)</sup>	TPS54318	UNIT
	RTE (WQFN)		
	16 PINS		
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	50	°C/W
R <sub>θJA</sub>	Junction-to-ambient thermal resistance <sup>(3)</sup>	37	
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	59.1	
R <sub>θJB</sub>	Junction-to-board thermal resistance	23.1	
Ψ <sub>JT</sub>	Junction-to-top characterization parameter	1.4	
Ψ <sub>JB</sub>	Junction-to-board characterization parameter	23.1	
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	7.9	

(1) Unless otherwise specified, metrics listed in this table refer to JEDEC high-K board measurements

(2) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, [SPRA953](#).

(3) Test Board Conditions:

- (a) 2 inches × 2 inches, 4 layers, thickness: 0.062 inch
- (b) 2 oz. copper traces located on the top of the PCB
- (c) 2 oz. copper ground planes located on the two internal layers and bottom layer
- (d) 4 thermal vias (10 mil) located under the device package

## 6.5 Electrical Characteristics

$-40^\circ\text{C} \leq T_J \leq 150^\circ\text{C}$ ,  $2.95 \leq V_{\text{VIN}} \leq 6 \text{ V}$  (unless otherwise noted) over operating free-air temperature range

## 7 Detailed Description

### 7.1 Overview

The TPS54318 device is a 6-V, 3-A, synchronous step-down (buck) converter with two integrated n-channel MOSFETs. To improve performance during line and load transients the device implements a constant frequency, peak current mode control which reduces output capacitance and simplifies external frequency compensation design. The wide supported switching frequency range of 200 kHz to 2000 kHz allows for efficiency and size optimization when selecting the output filter components. The switching frequency is adjusted using a resistor to ground on the RT/CLK pin. The device has an internal phase lock loop (PLL) on the RT/CLK pin that is used to synchronize the power switch turn on to a falling edge of an external system clock.

The TPS54318 device has a typical default start up voltage of 2.6 V. The EN pin has an internal pull-up current source that can be used to adjust the input voltage under voltage lockout (UVLO) with two external resistors. In addition, the pull up current provides a default condition when the EN pin is floating for the device to operate. The total operating current for the TPS54318 device is 350  $\mu$ A when not switching and under no load. When the device is disabled, the supply current is less than 5  $\mu$ A.

The integrated, 30-m $\Omega$  MOSFETs allow for high-efficiency power supply designs with continuous output currents up to 3 amperes.

The TPS54318 device reduces the external component count by integrating the boot recharge diode. The bias voltage for the integrated high-side MOSFET is supplied by a capacitor on the BOOT to PH pin. The boot capacitor voltage is monitored by an UVLO circuit and turns off the high-side MOSFET when the voltage falls below a preset threshold. This BOOT circuit allows the TPS54318 device to operate approaching 100%. The output voltage can be stepped down to as low as the 0.8 V reference.

The TPS54318 device has a power good comparator (PWRGD) with 2% hysteresis.

The TPS54318 device minimizes excessive output overvoltage transients by taking advantage of the overvoltage power good comparator. When the regulated output voltage is greater than 109% of the nominal voltage, the overvoltage comparator is activated, and the high-side MOSFET is turned off and masked from turning on until the output voltage is lower than 105%.

The SS (soft-start) pin is used to minimize inrush currents or provide power supply sequencing during power up. A small value capacitor should be coupled to the pin for soft-start. The SS pin is discharged before the output power up to ensure a repeatable re-start after an over-temperature fault, UVLO fault or disabled condition.

The use of a frequency-foldback circuit reduces the switching frequency during startup and over current fault conditions to help limit the inductor current.

## 7.2 Functional Block Diagram

## 7.3 Feature Description

### 7.3.1 Fixed Frequency PWM Control

The TPS54318 device uses an adjustable fixed-frequency peak-current-mode control. The output voltage is compared through external resistors on the VSENSE to pin an internal voltage reference by an error amplifier which drives the COMP pin. An internal oscillator initiates the turnon of the high-side power switch. The error amplifier output is compared to the high-side power-switch current. When the power switch reaches the COMP voltage, the high-side power switch is turned off and the low-side power switch is turned on.

The COMP pin voltage increases and decreases as the peak switch current increases and decreases. The device implements a current-limit function by clamping the COMP pin voltage to a maximum value, which limits the maximum peak current the device supplies. The device also implements a minimum COMP pin voltage clamp for improved transient response. When the COMP pin voltage is pushed low to the minimum clamp, such as during a load release event, turn-on of the high-side power switch is inhibited.

### 7.3.2 Slope Compensation and Output Current

The TPS54318 device adds a compensating ramp to the switch current signal. This slope compensation prevents sub-harmonic oscillations as duty cycle increases. The available peak inductor current remains constant over the full duty cycle range.

### 7.3.3 Bootstrap Voltage (Boot) and Low Dropout Operation

The TPS54318 device has an integrated boot regulator and requires a small ceramic capacitor between the BOOT and PH pin to provide the gate drive voltage for the high-side MOSFET. The value of the ceramic capacitor should be 0.1  $\mu$ F. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating of 10 V or higher is recommended because of the stable characteristics overtemperature and voltage.

## Feature Description (continued)

To improve drop out, the TPS54318 device is designed to operate at 100% duty cycle as long as the BOOT to PH pin voltage is greater than 2.5 V. The high-side MOSFET is turned off using an UVLO circuit, allowing for the low-side MOSFET to conduct when the voltage from BOOT to PH drops below 2.5 V. Because the supply current sourced from the BOOT pin is low, the high-side MOSFET can remain on for more switching cycles than are required to refresh the capacitor, thus the effective duty cycle of the switching regulator is high.

### 7.3.4 Error Amplifier

The TPS54318 device has a transconductance amplifier. The error amplifier compares the VSENSE voltage to the lower of the SS pin voltage or the internal 0.8 V voltage reference. The transconductance of the error amplifier is 225  $\mu\text{A}/\text{V}$  during normal operation. When the voltage of VSENSE pin is below 0.8 V and the device is regulating using the SS voltage, the transconductance is 70  $\mu\text{A}/\text{V}$ . The frequency compensation components are placed between the COMP pin and ground.

### 7.3.5 Voltage Reference

The voltage reference system produces a precise  $\pm 1\%$  voltage reference overtemperature by scaling the output of a temperature stable bandgap circuit. The bandgap and scaling circuits produce 0.8 V at the non-inverting input of the error amplifier.

### 7.3.6 Adjusting the Output Voltage

The output voltage is set with a resistor divider from the output node to the VSENSE pin. It is recommended to use divider resistors with 1% tolerance or better. Start with a value of 100 k $\Omega$  for the R1 resistor and use [Equation 1](#) to calculate R2. To improve efficiency at very light loads, consider using larger resistor values. If the values are too high, the regulator is more susceptible to noise and voltage errors from the VSENSE input current are noticeable.

$$R_2 = R_1 \times \left( \frac{0.8 \text{ V}}{V_O - 0.8 \text{ V}} \right) \quad (1)$$

**Figure 23. Voltage Divider Circuit**

### 7.3.7 Enable and Adjusting Undervoltage Lockout

The TPS54318 device is disabled when the VIN pin voltage falls below 2.6 V. If an application requires a higher under-voltage lockout (UVLO), use the EN pin as shown in [Figure 24](#) to adjust the input voltage UVLO by using two external resistors. It is recommended to use the enable resistors to set the UVLO falling threshold ( $V_{STOP}$ ) above 2.7 V. The rising threshold ( $V_{START}$ ) should be set to provide enough hysteresis to allow for any input supply variations. The EN pin has an internal pull-up current source that provides the default condition of the TPS54318 device operating when the EN pin floats. Once the EN pin voltage exceeds 1.25 V, an additional 2.55  $\mu\text{A}$  of hysteresis is added. When the EN pin is pulled below 1.18 V, the 2.55  $\mu\text{A}$  is removed. This additional current facilitates input voltage hysteresis.

## Feature Description (continued)

**Figure 24. Adjustable Undervoltage Lockout**

$$R1 = \frac{0.944 \cdot V_{START} - V_{STOP}}{2.59 \times 10^{-6}} \quad (2)$$

$$R2 = \frac{1.18 \cdot R1}{V_{STOP} - 1.18 + R1 \cdot 3.2 \times 10^{-6}} \quad (3)$$

### 7.3.8 Soft-Start Pin

The TPS54318 device regulates to the lower of the SS pin and the internal reference voltage. A capacitor on the SS pin to ground implements a soft-start time. The TPS54318 device has an internal pull-up current source of 1.8  $\mu$ A which charges the external soft-start capacitor. [Equation 4](#) calculates the required soft-start capacitor value where  $t_{SS}$  is the desired soft-start time in ms,  $I_{SS}$  is the internal soft-start charging current of 1.8  $\mu$ A, and  $V_{REF}$  is the internal voltage reference of 0.8 V. it is recommended to maintain the soft-start time in the range between 1 ms and 10 ms.

$$C_{SS} = \frac{I_{SS} \times t_{SS}}{V_{REF}}$$

where

- $C_{SS}$  is in nF
  - $t_{SS}$  is in ms
  - $I_{SS}$  is in  $\mu$ A
  - $V_{REF}$  is in V
- (4)

If during normal operation, the input voltage goes below the UVLO, EN pin pulled below 1.2 V, or a thermal shutdown event occurs, the TPS54318 device stops switching and the SS is discharged to 0 volts before reinitiating a powering up sequence.

### 7.3.9 Sequencing

Many of the common power supply sequencing methods can be implemented using the SS, EN and PWRGD pins. The sequential method can be implemented using an open drain or collector output of a power on reset pin of another device. [Figure 25](#) shows the sequential method. The power good is coupled to the EN pin on the TPS54318 device which enables the second power supply once the primary supply reaches regulation.

Ratiometric start up can be accomplished by connecting the SS pins together. The regulator outputs ramp up and reach regulation at the same time. When calculating the soft-start time the pull up current source must be doubled in [Equation 4](#). The ratiometric method is shown in [Figure 27](#).

## Feature Description (continued)

**Figure 27. Ratiometric Start-Up Schematic**

**Figure 28. Ratiometric Start-Up Using Coupled SS Pins**

### 7.3.10 Constant Switching Frequency and Timing Resistor (RT/CLK Pin)

The switching frequency of the TPS54318 device is adjustable over a wide range from 200 kHz to 2000 kHz by placing a maximum of 1000 kΩ and minimum of 85 kΩ, respectively, on the RT/CLK pin. An internal amplifier holds this pin at a fixed voltage when using an external resistor to ground to set the switching frequency. The RT/CLK is typically 0.5 V. To determine the timing resistance for a given switching frequency, use the curve in Figure 5 or Figure 6 or Equation 5.

$$R_{RT} = \frac{311890}{(f_{SW})^{1.0793}}$$

where

- $R_{RT}$  is in kΩ
  - $f_{SW}$  is in kHz
- (5)

$$f_{SW} = \frac{133870}{(R_{RT})^{0.9393}}$$

where

- $R_{RT}$  is in kΩ
  - $f_{SW}$  is in kHz
- (6)

To reduce the solution size one would typically set the switching frequency as high as possible, but tradeoffs of the efficiency, maximum input voltage and minimum controllable on time should be considered.

## Feature Description (continued)

The minimum controllable on time is typically 60 ns at full current load and 110 ns at no load, and limits the maximum operating input voltage or output voltage.

### 7.3.11 Overcurrent Protection

The TPS54318 device implements a cycle-by-cycle current limit. During each switching cycle the high-side switch current is compared to the voltage on the COMP pin. When the instantaneous switch current intersects the COMP voltage, the high-side switch is turned off. During overcurrent conditions that pull the output voltage low, the error amplifier responds by driving the COMP pin high, increasing the switch current. The error amplifier output is clamped internally. This clamp functions as a switch current limit.

### 7.3.12 Frequency Shift

To operate at high switching frequencies and provide protection during overcurrent conditions, the TPS54318 device implements a frequency shift. If frequency shift was not implemented, during an overcurrent condition the low-side MOSFET may not be turned off long enough to reduce the current in the inductor, causing a current runaway. With frequency shift, during an overcurrent condition the switching frequency is reduced from 100%, then 75%, then 50%, then 25% as the voltage decreases from 0.8 to 0 volts on VSENSE pin to allow the low-side MOSFET to be off long enough to decrease the current in the inductor. During start-up, the switching frequency increases as the voltage on VSENSE increases from 0 to 0.8 volts. See [Figure 7](#) for details.

### 7.3.13 Reverse Overcurrent Protection

The TPS54318 device implements low-side current protection by detecting the voltage across the low-side MOSFET. When the converter sinks current through its low-side FET, the control circuit turns off the low-side MOSFET if the reverse current is more than 1.3 A. By implementing this additional protection scheme, the converter is able to protect itself from excessive current during power cycling and start-up into pre-biased outputs.

### 7.3.14 Synchronize Using the RT/CLK Pin

The RT/CLK pin is used to synchronize the converter to an external system clock. See [Figure 29](#). To implement the synchronization feature in a system, connect a square wave to the RT/CLK pin with an on time of at least 75ns. If the pin is pulled above the PLL upper threshold, a mode change occurs and the pin becomes a synchronization input. The internal amplifier is disabled and the pin is a high impedance clock input to the internal PLL. If clocking edges stop, the internal amplifier is re-enabled and the mode returns to the frequency set by the resistor. The square wave amplitude at this pin must transition lower than 0.6 V and higher than 1.6 V typically. The recommended synchronization frequency range is 300 kHz to 2000 kHz. If the external system clock is to be removed, TI recommends that it be removed on the falling edge of the clock.

**Figure 29. Synchronizing to a System Clock**

**Figure 30. Plot of Synchronizing to System Clock**

## **Feature Description (continued)**

### 7.3.15 Power Good (PWRGD Pin)

The PWRGD pin output is an open drain MOSFET. The output is pulled low when the VSENSE voltage enters the fault condition by falling below 91% or rising above 107% of the nominal internal reference voltage. There is a 2% hysteresis on the threshold voltage, so when the VSENSE voltage rises to the good condition above 93% or falls below 105% of the internal voltage reference the PWRGD output MOSFET is turned off. It is recommended to use a pull-up resistor between the values of 1 kΩ and 100 kΩ to a voltage source that is 6 V or less. The PWRGD is in a valid state once the VIN input voltage is greater than 1.2 V.

### 7.3.16 Overvoltage Transient Protection

The TPS54318 device incorporates an overvoltage transient protection (OVTP) circuit to minimize voltage overshoot when recovering from output fault conditions or strong unload transients. The OVTP feature minimizes the output overshoot by implementing a circuit to compare the VSENSE pin voltage to the OVTP threshold which is 109% of the internal voltage reference. If the VSENSE pin voltage is greater than the OVTP threshold, the high-side MOSFET is disabled preventing current from flowing to the output and minimizing output overshoot. When the VSENSE voltage drops lower than the OVTP threshold the high-side MOSFET is allowed to turn on the next clock cycle.

### 7.3.17 Thermal Shutdown

The device implements an internal thermal shutdown to protect itself if the junction temperature exceeds 175°C. The thermal shutdown forces the device to stop switching when the junction temperature exceeds the thermal trip threshold. Once the die temperature decreases below 160°C, the device reinitiates the power up sequence by discharging the SS pin to 0 volts. The thermal shutdown hysteresis is 15°C.

## 7.4 Device Functional Modes

#### 7.4.1 Small Signal Model for Loop Response

[Figure 31](#) shows an equivalent model for the TPS54318 device control loop which can be modeled in a circuit simulation program to check frequency response and dynamic load response. The error amplifier is a transconductance amplifier with a  $g_M$  of  $225 \mu\text{A/V}$ . The error amplifier can be modeled using an ideal voltage controlled current source. The resistor  $R_{\text{OUT(ea)}}$  and capacitor  $C_{\text{OUT(ea)}}$  model the open loop gain and frequency response of the amplifier. The 1-mV AC voltage source between the nodes a and b effectively breaks the control loop for the frequency response measurements. Plotting a/c shows the small signal response of the frequency compensation. Plotting a/b shows the small signal response of the overall loop. The dynamic loop response can be checked by replacing the  $R_{\text{LOAD}}$  with a current source with the appropriate load step amplitude and step rate in a time domain analysis.

**Figure 31. Small Signal Model for Loop Response**

## Device Functional Modes (continued)

### 7.4.2 Simple Small Signal Model for Peak Current Mode Control

Figure 32 is a simple small signal model that can be used to understand how to design the frequency compensation. The TPS54318 device power stage can be approximated to a voltage controlled current source (duty cycle modulator) supplying current to the output capacitor and load resistor. The control to output transfer function is shown in Equation 7 and consists of a dc gain, one dominant pole and one ESR zero. The quotient of the change in switch current and the change in COMP pin voltage (node c in Figure 31) is the power stage transconductance. The  $g_m$  for the TPS54318 device is 13 A/V. The low frequency gain of the power stage frequency response is the product of the transconductance and the load resistance as shown in Equation 8. As the load current increases and decreases, the low frequency gain decreases and increases, respectively. This variation with load may seem problematic at first glance, but the dominant pole moves with load current [see Equation 9]. The combined effect is highlighted by the dashed line in the right half of Figure 33. As the load current decreases, the gain increases and the pole frequency lowers, keeping the 0-dB crossover frequency the same for the varying load conditions which makes it easier to design the frequency compensation.

**Figure 32. Simple Small Signal Model**

**Figure 33. Frequency Response**

$$\frac{V_{OUT}}{V_C} = Adc \times \frac{1 + \left( \frac{s}{2\pi \times f_Z} \right)}{1 + \left( \frac{s}{2\pi \times f_P} \right)} \quad (7)$$

$$Adc = g_{M(PS)} \times R_{LOAD} \quad (8)$$

$$f_P = \frac{1}{C_{OUT} \times R_{LOAD} \times 2\pi} \quad (9)$$

$$f_Z = \frac{1}{C_{OUT} \times R_{ESR} \times 2\pi} \quad (10)$$

### 7.4.3 Small Signal Model for Frequency Compensation

The TPS54318 device uses a transconductance amplifier for the error amplifier and readily supports two of the commonly used frequency compensation circuits. The compensation circuits are shown in Figure 34. The Type-II circuits are most likely implemented in high bandwidth power supply designs using low ESR output capacitors. In Type-IIA, one additional high frequency pole is added to attenuate high-frequency noise.

## Device Functional Modes (continued)

**Figure 34. Types of Frequency Compensation**

The design guidelines for TPS54318 device loop compensation are as follows:

- Calculate the modulator pole ( $f_{P(MOD)}$ ) and the esr zero, ( $f_{Z1}$ ) using [Equation 11](#) and [Equation 12](#). If the output voltage is a high percentage of the capacitor rating it may be necessary to derate the output capacitor ( $C_{OUT}$ ). Use the capacitor manufacturer information to derate the capacitor value. Use [Equation 13](#) and [Equation 14](#) to estimate a starting point for the crossover frequency,  $f_C$ . [Equation 13](#) shows the geometric mean of the modulator pole and the ESR zero and [Equation 14](#) is the mean of modulator pole and the switching frequency. Use the lower value of [Equation 13](#) or [Equation 14](#) as the maximum crossover frequency.

$$f_{P(mod)} = \frac{I_{OUT(max)}}{2\pi \times V_{OUT} \times C_{OUT}} \quad (11)$$

$$f_{Z1} = \frac{1}{C_{OUT} \times R_{ESR} \times 2\pi} \quad (12)$$

$$f_C = \sqrt{f_{P(mod)} + f_{Z1}} \quad (13)$$

$$f_C = \sqrt{f_{P(mod)} \times \frac{f_{SW}}{2}} \quad (14)$$

- Calculate resistor R3. [Equation 15](#) shows the calculation for resistor R3.

$$R3 = \frac{2\pi \times f_C \times V_{OUT} \times C_{OUT}}{g_{M(ea)} \times V_{REF} \times g_{M(ps)}} \quad (15)$$

where

- $g_{M(ea)}$  is the amplifier gain ( $225 \mu\text{A/V}$ )
- $g_{M(ps)}$  is the power stage gain ( $13 \text{ A/V}$ )

- Place a compensation zero at the dominant pole.  $f_p$ . [Equation 16](#) shows the calculation for capacitor C1.

$$f_p = \frac{1}{C_{OUT} \times R_{LOAD} \times 2\pi} \quad (16)$$

$$C1 = \frac{R_L \times C_{OUT}}{R3} \quad (17)$$

- Capacitor C2 is optional. It can be used to cancel the zero from the output capacitor ( $C_{OUT}$ ) ESR.

$$C2 = \frac{R_{ESR} \times C_{OUT}}{R3} \quad (18)$$

## 8 Application and Implementation

## **NOTE**

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

## 8.1 Application Information

This design example describes a high-frequency switching regulator design using ceramic output capacitors. This design is available as the HPA512 ([SLVU330](#)) evaluation module (EVM).

## 8.2 Typical Application

This section details a high-frequency, 1.8-V output power supply design application with adjusted UVLO.

**Figure 35. Typical Application Schematic, TPS54318**

### **8.2.1 Design Requirements**

**Table 1. Design Parameters**

PARAMETER	NOTES AND CONDITIONS	MIN	TYP	MAX	UNIT
V <sub>IN</sub>	Input voltage	Operating	3	3.3	6
V <sub>START</sub>	Start input voltage	Rising		3.1	V
V <sub>STOP</sub>	Stop input voltage	Falling		2.8	
V <sub>OUT</sub>	Output voltage			1.8	V
ΔV <sub>OUT</sub>	Transient response	1-A to 2-A load step		3%	
I <sub>OUT(max)</sub>	Maximum output current			3	A
V <sub>OUT(ripple)</sub>	Output voltage ripple			30	mV <sub>P-P</sub>
f <sub>SW</sub>	Switching frequency			1	MHz

## 8.2.2 Detailed Design Procedure

### 8.2.2.1 Step One: Select the Switching Frequency

Choose the highest switching frequency possible in order to produce the smallest solution size. The high switching frequency allows for lower valued inductors and smaller output capacitors compared to a power supply that switches at a lower frequency. However, the highest switching frequency causes extra switching losses, which in turn decrease the device performance. The device is capable of operating between 200 kHz and 2 MHz. Select a moderate switching frequency of 1 MHz in order to achieve both a small solution size and a high-efficiency operation. Using [Equation 5](#), R<sub>4</sub> is calculated to 180 kΩ. A standard 1%, 182-kΩ resistor is used in the design.

### 8.2.2.2 Step Two: Select the Output Inductor

The inductor selected must operate across the entire TPS54318 device input voltage range. To calculate the value of the output inductor, use [Equation 19](#). K<sub>IND</sub> is a coefficient that represents the amount of inductor ripple current relative to the maximum output current. The inductor ripple current is filtered by the output capacitor. Therefore, choosing high inductor ripple currents impacts the selection of the output capacitor since the output capacitor must have a ripple current rating equal to or greater than the inductor ripple current. In general, the inductor ripple value is at the discretion of the designer; however, K<sub>IND</sub> is normally from 0.1 to 0.3 for the majority of applications.

For this design example, use a K<sub>IND</sub> of 0.3 and the inductor value is calculated to be 1.40 μH. For this design, use an inductor with the nearest standard value of 1.50 μH. For the output filter inductor, it is important that the RMS current and saturation current ratings not be exceeded. The RMS and peak inductor current can be calculated in [Equation 21](#) and [Equation 22](#).

For this design, the RMS inductor current is 3.01 A and the peak inductor current is 3.42 A. The chosen inductor is a Coilcraft XPL7030-152ML. It has a RMS current rating of 12.3 A and a saturation current rating of 20.2 A. The current ratings for this exceed the requirement, but the inductor was chosen for small physical size and low series resistance for high efficiency.

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the calculated peak inductor current level calculated above. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative approach is to specify an inductor with a saturation current rating equal to or greater than the switch current limit rather than the peak inductor current.

$$L_1 = \frac{(V_{IN(max)} - V_{OUT})}{I_{OUT} \times K_{IND}} \times \frac{V_{OUT}}{V_{IN(max)} \times f_{SW}} \quad (19)$$

$$I_{RIPPLE} = \frac{(V_{IN(max)} - V_{OUT})}{L_1} \times \frac{V_{OUT}}{V_{IN(max)} \times f_{SW}} \quad (20)$$

$$I_{L(rms)} = \sqrt{(I_{OUT})^2 + \frac{1}{12} \times \left( \frac{V_{OUT} \times (V_{IN(max)} - V_{OUT})}{V_{IN(max)} \times L_1 \times f_{SW}} \right)^2} \quad (21)$$

$$I_{L(peak)} = I_{OUT} + \left( \frac{I_{RIPPLE}}{2} \right) \quad (22)$$

### 8.2.2.3 Step Three: Choose the Output Capacitor

There are three primary considerations for selecting the value of the output capacitor. The output capacitor determines the modulator pole, the output voltage ripple, and how the regulator responds to a large change in load current. The output capacitance needs to be selected based on the more stringent of these three criteria.

The desired response to a large change in the load current is the first criteria. The output capacitor needs to supply the load with current when the regulator cannot. This situation would occur if there are desired hold-up times for the regulator where the output capacitor must hold the output voltage above a certain level for a specified amount of time after the input power is removed. The regulator is temporarily not able to supply sufficient output current if there is a large, fast increase in the current needs of the load such as transitioning from no load to a full load. The regulator usually needs two or more clock cycles for the control loop to see the change in load current and output voltage and adjust the duty cycle to react to the change. The output capacitor must be sized to supply the extra current to the load until the control loop responds to the load change. The output capacitance must be large enough to supply the difference in current for two clock cycles while only allowing a tolerable amount of droop in the output voltage. [Equation 25](#) shows the necessary minimum output capacitance.

For this example, the transient load response is specified as a 3% change in  $V_{OUT}$  for a load step from 1.25 A (50% load) to 2.75 A (100%).

$$\Delta I_{OUT} = 2.75 - 1.25 = 1.5 \text{ A} \quad (23)$$

$$\Delta V_{OUT} = 0.03 \times 1.8 = 0.054 \text{ V} \quad (24)$$

Using these numbers gives a minimum capacitance of 56  $\mu\text{F}$ . This value does not take the ESR of the output capacitor into account in the output voltage change. For ceramic capacitors, the ESR is usually small enough to ignore in this calculation.

[Equation 26](#) calculates the minimum output capacitance needed to meet the output voltage ripple specification. Where  $f_{SW}$  is the switching frequency,  $V_{RIPPLE}$  is the maximum allowable output voltage ripple, and  $I_{RIPPLE}$  is the inductor ripple current. In this case, the maximum output voltage ripple is 30 mV. [Equation 26](#) yields 3.2  $\mu\text{F}$ .

$$C_{OUT(\text{transient})} > \frac{2 \times \Delta I_{OUT}}{f_{SW} \times \Delta V_{OUT}} \quad (25)$$

$$C_{OUT(\text{ripple})} > \frac{I_{Ripple}}{8 \times f_{SW} \times V_{OUT(\text{ripple})}} \quad (26)$$

where

- $\Delta I_{OUT}$  is the load step size
- $\Delta V_{OUT}$  is the acceptable output deviation
- $f_{SW}$  is the switching frequency
- $I_{Ripple}$  is the inductor ripple current
- $V_{OUT(\text{ripple})}$  is the acceptable DC output voltage ripple

[Equation 27](#) calculates the maximum ESR an output capacitor can have to meet the output voltage ripple specification. [Equation 27](#) indicates the ESR should be less than 39 m $\Omega$ . In this case, the ESR of the ceramic capacitor is much less than 39 m $\Omega$ .

Additional capacitance de-ratings for aging, temperature and DC bias should be factored in which increases this minimum value. For this example, three 22- $\mu\text{F}$ , 10-V, X5R ceramic capacitors with 3 m $\Omega$  of ESR are used.

Capacitors generally have limits to the amount of ripple current they can handle without failing or producing excess heat. An output capacitor that can support the inductor ripple current must be specified. Some capacitor data sheets specify the RMS (root mean square) value of the maximum ripple current. [Equation 28](#) can be used to calculate the RMS ripple current the output capacitor needs to support. For this application, [Equation 28](#) yields 222 mA.

$$R_{ESR} < \frac{V_{OUT(\text{ripple})}}{I_{Ripple}} \quad (27)$$

$$I_{CO(\text{rms})} = \frac{V_{OUT} \times (V_{IN(\text{max})} - V_{OUT})}{\sqrt{12} \times V_{IN(\text{max})} \times L_1 \times f_{SW}} \quad (28)$$

#### **8.2.2.4 Step Four: Select the Input Capacitor**

The TPS54318 device requires a high quality ceramic, type X5R or X7R, input decoupling capacitor of at least 4.7  $\mu\text{F}$  of effective capacitance and in some applications a bulk capacitance. The effective capacitance includes any DC bias effects. The voltage rating of the input capacitor must be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum input current ripple of the device. The input ripple current can be calculated using [Equation 29](#).

The value of a ceramic capacitor varies significantly over temperature and the amount of DC bias applied to the capacitor. The capacitance variations due to temperature can be minimized by selecting a dielectric material that is stable over temperature. X5R and X7R ceramic dielectrics are usually selected for power regulator capacitors because they have a high capacitance to volume ratio and are fairly stable over temperature. The output capacitor must also be selected with the dc bias taken into account. The capacitance value of a capacitor decreases as the dc bias across a capacitor increases.

For this example design, a ceramic capacitor with at least a 10 V voltage rating is required to support the maximum input voltage. For this example, one 10  $\mu\text{F}$  and one 0.1  $\mu\text{F}$  10 V capacitors in parallel have been selected. The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using [Equation 30](#).

$$I_{CIN(rms)} = I_{OUT} \times \sqrt{\frac{V_{OUT}}{V_{IN(min)}} \times \frac{(V_{IN(min)} - V_{OUT})}{V_{IN(min)}}} \quad (29)$$

$$\Delta V_{IN} = \frac{I_{OUT(max)} \times 0.25}{C_{IN} \times f_{SW}} \quad (30)$$

Using the design example values,  $I_{OUT(max)} = 3 \text{ A}$ ,  $C_{IN} = 10 \mu\text{F}$ ,  $f_{SW} = 1 \text{ MHz}$ , yields an input voltage ripple of 51 mV and a rms input ripple current of 1.47  $\text{A}$ .

#### **8.2.2.5 Step Five: Minimum Load DC COMP Voltage**

The TPS54318 implements a minimum COMP voltage clamp for improved load-transient response. The COMP voltage tracks the peak inductor current, increasing as the peak inductor current increases, and decreases as the peak inductor current decreases. During a severe load-dump event, for instance, the COMP voltage decreases suddenly, falls below the minimum clamp value, then settles to a lower DC value as the control loop compensates for the transient event. During the time when COMP reaches the minimum clamp voltage, turnon of the high-side power switch is inhibited, keeping the low-side power switch on to discharge the output voltage overshoot more quickly.

Proper application circuit design must ensure that the minimum load steady-state COMP voltage is above the +3 sigma minimum clamp to avoid unwanted inhibition of the high side power switch. For a given design, the steady-state DC level of COMP must be measured at the minimum designed load and at the maximum designed input voltage, then compared to the minimum COMP clamp voltage shown in [Figure 22](#). These conditions give the minimum COMP voltage for a given design. Generally, the COMP voltage and minimum clamp voltage move by about the same amount with temperature. Increasing the minimum load COMP voltage is accomplished by decreasing the output inductor value or the switching frequency used in a given design.

#### **8.2.2.6 Step Six: Choose the Soft-Start Capacitor**

The soft-start capacitor determines the minimum amount of time it takes for the output voltage to reach its nominal programmed value during power up. This is useful if a load requires a controlled voltage slew rate. This is also used if the output capacitance is very large and would require large amounts of current to quickly charge the capacitor to the output voltage level. The large currents necessary to charge the capacitor may make the device reach the current limit or excessive current draw from the input power supply may cause the input voltage rail to sag. Limiting the output voltage slew rate solves both of these problems.

The soft-start capacitor value can be calculated using [Equation 31](#). For the example circuit, the soft-start time is not too critical since the output capacitor value is 66  $\mu\text{F}$  which does not require much current to charge to 1.8 V. The example circuit has the soft-start time set to an arbitrary value of 4 ms which requires a 10 nF capacitor. In the device,  $I_{SS}$  is 2  $\mu\text{A}$  and  $V_{REF}$  is 0.8 V. For this application, maintain the soft-start time in the range between 1 ms and 10 ms.

$$C_{SS} = \frac{I_{SS} \times t_{SS}}{V_{REF}}$$

where

- $C_{SS}$  is in nF
  - $I_{SS}$  is in  $\mu$ A
  - $t_{SS}$  is in ms
  - $V_{REF}$  is in V
- (31)

### 8.2.2.7 Step Seven: Select the Bootstrap Capacitor

A 0.1- $\mu$ F ceramic capacitor must be connected between the BOOT to PH pin for proper operation. It is recommended to use a ceramic capacitor with X5R or better grade dielectric. The capacitor should have 10 V or higher voltage rating.

### 8.2.2.8 Step Eight: Undervoltage Lockout Threshold

The undervoltage lockout (UVLO) can be adjusted using an external voltage divider on the EN pin of the TPS54318. The UVLO has two thresholds, one for power up when the input voltage is rising and one for power down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 3.1 V ( $V_{START}$ ). Switching continues until the input voltage falls below 2.8 V ( $V_{STOP}$ ).

The programmable UVLO and enable voltages are set using a resistor divider between the VIN pin and GND to the EN pin. [Equation 32](#) and [Equation 33](#) can be used to calculate the resistance values necessary. From [Equation 32](#) and [Equation 33](#), a 48.7 k $\Omega$  between the VIN pin and the EN pin and a 32.4-k $\Omega$  resistor between the EN pin and GND are required to produce the 3.1-V start voltage and the 2.8-V stop voltage.

$$R1 = \frac{0.944 \cdot V_{START} - V_{STOP}}{2.59 \times 10^{-6}} \quad (32)$$

$$R2 = \frac{1.18 \cdot R1}{V_{STOP} - 1.18 + R1 \cdot 3.2 \times 10^{-6}} \quad (33)$$

### 8.2.2.9 Step Nine: Select Output Voltage and Feedback Resistors

For the example design, 100 k $\Omega$  was selected for R6. Using [Equation 34](#), R7 is calculated as 80 k $\Omega$ . The nearest standard 1% resistor is 80.6 k $\Omega$ .

$$R7 = \frac{V_{ref}}{V_{OUT} - V_{ref}} R6 \quad (34)$$

#### 8.2.2.9.1 Output Voltage Limitations

Due to the internal design of the TPS54318, there are limitations to the minimum and maximum achievable output voltages. The output voltage can never be lower than the internal voltage reference of 0.8 V. Above 0.8 V, the output voltage may be limited by the minimum controllable on time. The minimum output voltage in this case is given by [Equation 35](#). There is also a maximum achievable output voltage which is limited by the minimum off time. The maximum output voltage is given by [Equation 36](#). These equations represent the results when the power MOSFETs are matched. Refer to [SLYT293](#) for more information.

$$V_{OUT(min)} = t_{ON(min)} \times f_{SW(max)} \times V_{IN(max)} - I_{OUT(min)}(R_{LS(min)} + R_{DCR})$$

where

- $V_{OUT(min)}$  is the minimum achievable output voltage
  - $t_{ON(min)}$  is the minimum controllable on-time (110 nsec typical)
  - $f_{SW(max)}$  is the maximum switching frequency including tolerance
  - $V_{IN(max)}$  is the maximum input voltage
  - $I_{OUT(min)}$  is the minimum load current
  - $R_{LS(min)}$  is the minimum low-side MOSFET on-resistance. (30 m $\Omega$  typical)
  - $R_{DCR}$  is the series resistance of output inductor
- (35)

$$V_{OUT(max)} = (1 - t_{OFF(max)} f_{SW(max)}) V_{IN(min)} - I_{OUT(max)} (R_{LS(max)} + R_{DCR})$$

where

- $V_{OUT(max)}$  is the maximum achievable output voltage
  - $t_{OFF(max)}$  is the maximum, minimum controllable off time (60 ns typical)
  - $f_{SW(max)}$  is the maximum switching frequency including tolerance
  - $V_{IN(min)}$  is the minimum input voltage
  - $I_{OUT(max)}$  is the maximum load current
  - $R_{HS(max)}$  is the maximum high-side MOSFET on-resistance. (70 mΩ max)
  - $R_{DCR}$  is the series resistance of output inductor
- (36)

#### **8.2.2.10 Step 10: Select Loop Compensation Components**

There are several industry techniques used to compensate DC/DC regulators. The method presented here is easy to calculate and yields high phase margins. For most conditions, the regulator has a phase margin between 60 and 90 degrees. The method presented here ignores the effects of the slope compensation that is internal to the TPS54318. Because the slope compensation is ignored, the actual crossover frequency is usually lower than the crossover frequency used in the calculations. Use [SwitcherPro](#) software for a more accurate design.

To get started, the modulator pole,  $f_{P(mod)}$ , and the esr zero,  $f_{Z1}$  must be calculated using [Equation 37](#) and [Equation 38](#). For  $C_{OUT}$ , derating the capacitor is not needed as the 1.8 V output is a small percentage of the 10 V capacitor rating. If the output is a high percentage of the capacitor rating, use the capacitor manufacturer information to derate the capacitor value. Use [Equation 39](#) and [Equation 40](#) to estimate a starting point for the crossover frequency,  $f_C$ . For the example design,  $f_{P(mod)}$  is 4.02 kHz and  $f_{Z1}$  is 804 kHz. [Equation 39](#) is the geometric mean of the modulator pole and the esr zero and [Equation 40](#) is the mean of modulator pole and the switching frequency. [Equation 39](#) yields 56 kHz and [Equation 40](#) gives 44.8 kHz. Use the lower value of [Equation 39](#) or [Equation 40](#) as the maximum crossover frequency. For this example,  $f_C$  is 45 kHz. Next, the compensation components are calculated. A resistor in series with a capacitor is used to create a compensating zero. A capacitor in parallel to these two components forms the compensating pole (if needed).

$$f_{P(mod)} = \frac{I_{OUT(max)}}{2\pi \times V_{OUT} \times C_{OUT}} \quad (37)$$

$$f_{Z1} = \frac{1}{C_{OUT} \times R_{ESR} \times 2\pi} \quad (38)$$

$$f_C = \sqrt{f_{P(mod)} + f_{Z1}} \quad (39)$$

$$f_C = \sqrt{f_{P(mod)} \times \frac{f_{SW}}{2}} \quad (40)$$

The compensation design takes the following steps:

1. Set up the anticipated cross-over frequency. Use [Equation 41](#) to calculate the compensation network's resistor value. In this example, the anticipated cross-over frequency  $f_C$  is 45 kHz. The power stage gain ( $g_{M(ps)}$ ) is 13 A/V and the error amplifier gain ( $g_{M(ea)}$ ) is 225uA/V.

$$R3 = \frac{2\pi \times f_C \times V_{OUT} \times C_{OUT}}{g_{M(ea)} \times V_{REF} \times g_{M(ps)}} \quad (41)$$

2. Place compensation zero at the pole formed by the load resistor and the output capacitor. The compensation network's capacitor can be calculated from [Equation 42](#).

$$C3 = \frac{R_{OUT} \times C_{OUT}}{R3} \quad (42)$$

3. An additional pole can be added to attenuate high frequency noise. In this application, it is not necessary to add it.

From the procedures above, start with a 14.3 kΩ resistor and a 2760 pF capacitor. After prototyping and bode plot measurement, the optimized compensation network selected for this design includes a 14.3 kΩ resistor and a 2700 pF capacitor.

### 8.2.2.11 Power Dissipation Estimate

Use [Equation 43](#) through [Equation 52](#) to help estimate the device power dissipation under continuous conduction mode (CCM) operation. The power dissipation of the device ( $P_{TOT}$ ) includes conduction loss ( $P_{COND}$ ), dead time loss ( $P_D$ ), switching loss ( $P_{SW}$ ), gate drive loss ( $P_{GD}$ ) and supply current loss ( $P_Q$ ).

$$P_{COND} = (I_{OUT})^2 \times R_{DS(on)} \quad (43)$$

$$P_D = f_{SW} \times I_{OUT} \times 0.7 \times 60 \times (10)^{-9} \quad (44)$$

$$P_D = f_{SW} \times I_{OUT} \times 0.7 \times 60 \times (10)^{-9} \quad (45)$$

$$P_{SW} = 2 \times (V_{IN})^2 \times f_{SW} \times I_{OUT} \times 0.25 \times (10)^{-9} \quad (46)$$

$$P_{SW} = 2 \times (V_{IN})^2 \times f_{SW} \times I_{OUT} \times 0.25 \times (10)^{-9} \quad (47)$$

$$P_{GD} = 2 \times V_{IN} \times 3 \times (10)^{-9} \times f_{SW} \quad (48)$$

$$P_Q = 350 \times (10)^{-6} \times V_{IN} \quad (49)$$

where

- $I_{OUT}$  is the output current (A)
- $R_{DS(on)}$  is the on-resistance of the high-side MOSFET ( $\Omega$ )
- $V_{OUT}$  is the output voltage (V)
- $V_{IN}$  is the input voltage (V)
- $f_{SW}$  is the switching frequency (Hz)

$$P_{TOT} = P_{COND} + P_D + P_{SW} + P_{GD} + P_Q \quad (50)$$

For a given ambient temperature,

$$T_J = T_A + R_{TH} \times P_{TOT} \quad (51)$$

For maximum junction temperature ( $T_{J(max)} = 150^\circ\text{C}$ )

$$T_{A(max)} = T_{J(max)} - R_{TH} \times P_{TOT}$$

where

- $P_{TOT}$  is the total device power dissipation (W)
- $T_A$  is the ambient temperature ( $^\circ\text{C}$ )
- $T_J$  is the junction temperature ( $^\circ\text{C}$ )
- $R_{TH}$  is the thermal resistance of the package ( $^\circ\text{C}/\text{W}$ )
- $T_{J(max)}$  is maximum junction temperature ( $^\circ\text{C}$ )
- $T_{A(max)}$  is maximum ambient temperature ( $^\circ\text{C}$ )

Additional power can be lost in the regulator circuit due to the inductor ac and dc losses and trace resistance that impact the overall regulator efficiency. [Figure 36](#) and [Figure 37](#) show power dissipation for the EVM.

## 9 Power Supply Recommendations

These devices are designed to operate from an input voltage supply between 2.95 V and 6 V. This supply must be well regulated. Proper bypassing of input supplies and internal regulators is also critical for noise performance, as is PCB layout and grounding scheme. See the recommendations in the [Layout Guidelines](#) section.

## 10 Layout

### 10.1 Layout Guidelines

Layout is a critical portion of good power supply design. There are several signal paths that conduct fast changing currents or voltages that can interact with stray inductance or parasitic capacitance to generate noise or degrade the power supplies performance.

- Minimize the loop area formed by the bypass capacitor connections and the VIN pins. See [Figure 54](#) for a PCB layout example.
- The GND pins and AGND pin should be tied directly to the power pad under the TPS54318 device. The power pad should be connected to any internal PCB ground planes using multiple vias directly under the device. Additional vias can be used to connect the top-side ground area to the internal planes near the input and output capacitors. For operation at full rated load, the top-side ground area along with any additional internal ground planes must provide adequate heat dissipating area.
- Place the input bypass capacitor as close to the device as possible.
- Route the PH pin to the output inductor. Because the PH connection is the switching node, place the output inductor close to the PH pins. Minimize the area of the PCB conductor to prevent excessive capacitive coupling.
- The boot capacitor must also be located close to the device.
- The sensitive analog ground connections for the feedback voltage divider, compensation components, soft-start capacitor and frequency set resistor should be connected to a separate analog ground trace as shown in [Figure 54](#).
- The RT/CLK pin is particularly sensitive to noise so the RT resistor should be located as close as possible to the device and routed with minimal trace lengths.
- The additional external components can be placed approximately as shown. It is possible to obtain acceptable performance with alternate PCB layouts, however, this layout has been shown to produce good results and can be used as a guide.

## 11 器件和文档支持

### 11.1 器件支持

#### 11.1.1 使用 WEBENCH® 工具创建定制设计

请单击此处，使用 TPS54318 器件并借助 WEBENCH® 电源设计器创建定制设计方案。

1. 首先键入输入电压 ( $V_{IN}$ )、输出电压 ( $V_{OUT}$ ) 和输出电流 ( $I_{OUT}$ ) 要求。
2. 使用优化器拨盘优化关键参数设计，如效率、封装和成本。
3. 将生成的设计与德州仪器 (TI) 的其他解决方案进行比较。

WEBENCH 电源设计器可提供定制原理图以及罗列实时价格和组件供货情况的物料清单。

在多数情况下，可执行以下操作：

- 运行电气仿真，观察重要波形以及电路性能
- 运行热性能仿真，了解电路板热性能
- 将定制原理图和布局方案导出至常用 CAD 格式
- 打印设计方案的 PDF 报告并与同事共享

有关 WEBENCH 工具的详细信息，请访问 [www.ti.com.cn/WEBENCH](http://www.ti.com.cn/WEBENCH)。

#### 11.1.2 开发支持

有关 SWIFT™ 文档的更多信息，请访问 TI 网站 [www.ti.com.cn/swift](http://www.ti.com.cn/swift)。

### 11.2 商标

SWIFT is a trademark of Texas Instruments.

WEBENCH is a registered trademark of Texas Instruments.

### 11.3 静电放电警告

### 11.4 Glossary

#### SLYZ022 — TI Glossary.

This glossary lists and explains terms, acronyms, and definitions.

## 12 机械、封装和可订购信息

以下页面包含机械、封装和可订购信息。这些信息是指定器件的最新可用数据。数据如有变更，恕不另行通知，且不会对此文档进行修订。如需获取此数据表的浏览器版本，请参阅左侧的导航栏。

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TPS54318RTER	ACTIVE	WQFN	RTE	16	3000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 150	54318	<b>Samples</b>
TPS54318RTET	ACTIVE	WQFN	RTE	16	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 150	54318	<b>Samples</b>

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## MECHANICAL DATA

RTE (S-PWQFN-N16)

PLASTIC QUAD FLATPACK NO-LEAD

4205254/D 01/11

- NOTES: A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.  
 B. This drawing is subject to change without notice.  
 C. Quad Flatpack, No-leads (QFN) package configuration.

- ⚠** The package thermal pad must be soldered to the board for thermal and mechanical performance.  
 See the Product Data Sheet for details regarding the exposed thermal pad dimensions.  
 E. Falls within JEDEC MO-220.

## THERMAL PAD MECHANICAL DATA

RTE (S-PWQFN-N16)

PLASTIC QUAD FLATPACK NO-LEAD

### THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.

## 重要声明

德州仪器 (TI) 公司有权按照最新发布的 JESD46 对其半导体产品和服务进行纠正、增强、改进和其他修改，并不再按最新发布的 JESD48 提供任何产品和服务。买方在下订单前应获取最新的相关信息，并验证这些信息是否完整且是最新的。

TI 公布的半导体产品销售条款 (<http://www.ti.com/sc/docs/stdterms.htm>) 适用于 TI 已认证和批准上市的已封装集成电路产品的销售。另有其他条款可能适用于其他类型 TI 产品及服务的使用或销售。

复制 TI 数据表上 TI 信息的重要部分时，不得变更该等信息，且必须随附所有相关保证、条件、限制和通知，否则不得复制。TI 对该等复制文件不承担任何责任。第三方信息可能受到其它限制条件的制约。在转售 TI 产品或服务时，如果存在对产品或服务参数的虚假陈述，则会失去相关 TI 产品或服务的明示或暗示保证，且构成不公平的、欺诈性商业行为。TI 对此类虚假陈述不承担任何责任。

买方和在系统中整合 TI 产品的其他开发人员（总称“设计人员”）理解并同意，设计人员在设计应用时应自行实施独立的分析、评价和判断，且应全权负责并确保应用的安全性，及设计人员的应用（包括应用中使用的所有 TI 产品）应符合所有适用的法律法规及其他相关要求。设计人员就自己设计的应用声明，其具备制订和实施下列保障措施所需的一切必要专业知识，能够（1）预见故障的危险后果，（2）监视故障及其后果，以及（3）降低可能导致危险的故障几率并采取适当措施。设计人员同意，在使用或分发包含 TI 产品的任何应用前，将彻底测试该等应用和该等应用所用 TI 产品的功能而设计。

TI 提供技术、应用或其他设计建议、质量特点、可靠性数据或其他服务或信息，包括但不限于与评估模块有关的参考设计和材料（总称“TI 资源”），旨在帮助设计人员开发整合了 TI 产品的应用，如果设计人员（个人，或如果是代表公司，则为设计人员的公司）以任何方式下载、访问或使用任何特定的 TI 资源，即表示其同意仅为该等目标，按照本通知的条款使用任何特定 TI 资源。

TI 所提供的 TI 资源，并未扩大或以其他方式修改 TI 对 TI 产品的公开适用的质保及质保免责声明；也未导致 TI 承担任何额外的义务或责任。TI 有权对其 TI 资源进行纠正、增强、改进和其他修改。除特定 TI 资源的公开文档中明确列出的测试外，TI 未进行任何其他测试。

设计人员只有在开发包含该等 TI 资源所列 TI 产品的应用时，才被授权使用、复制和修改任何相关单项 TI 资源。但并未依据禁止反言原则或其他法理授予您任何 TI 知识产权的任何其他明示或默示的许可，也未授予您 TI 或第三方的任何技术或知识产权的许可，该等产权包括但不限于任何专利权、版权、屏蔽作品权或与使用 TI 产品或服务的任何整合、机器制作、流程相关的其他知识产权。涉及或参考了第三方产品或服务的信息不构成使用此类产品或服务的许可或与其相关的保证或认可。使用 TI 资源可能需要您向第三方获得对该等第三方专利或其他知识产权的许可。

TI 资源系“按原样”提供。TI 兹免除对资源及其使用作出所有其他明确或默认的保证或陈述，包括但不限于对准确性或完整性、产权保证、无屡发故障保证，以及适销性、适合特定用途和不侵犯任何第三方知识产权的任何默认保证。TI 不负责任任何申索，包括但不限于因组合产品所致或与之有关的申索，也不为或对设计人员进行辩护或赔偿，即使该等产品组合已列于 TI 资源或其他地方。对因 TI 资源或其使用引起或与之有关的任何实际的、直接的、特殊的、附带的、间接的、惩罚性的、偶发的、从属或惩戒性损害赔偿，不管 TI 是否获悉可能会产生上述损害赔偿，TI概不负责。

除 TI 已明确指出特定产品已达到特定行业标准（例如 ISO/TS 16949 和 ISO 26262）的要求外，TI 不对未达到任何该等行业标准要求而承担责任。

如果 TI 明确宣称产品有助于功能安全或符合行业功能安全标准，则该等产品旨在帮助客户设计和创作自己的符合相关功能安全标准和要求的应用。在应用内使用产品的行为本身不会配有任何安全特性。设计人员必须确保遵守适用于其应用的相关安全要求和标准而设计。设计人员不可将任何 TI 产品用于关乎性命的医疗设备，除非已由各方获得授权的管理人员签署专门的合同对此类应用专门作出规定。关乎性命的医疗设备是指出现故障会导致严重身体伤害或死亡的医疗设备（例如生命保障设备、心脏起搏器、心脏除颤器、人工心脏泵、神经刺激器以及植入设备）。此类设备包括但不限于，美国食品药品监督管理局认定为 III 类设备的设备，以及在美国以外的其他国家或地区认定为同等类别设备的所有医疗设备。

TI 可能明确规定某些产品具备某些特定资格（例如 Q100、军用级或增强型产品）。设计人员同意，其具备一切必要专业知识，可以为自己的应用选择适合的产品，并且正确选择产品的风险由设计人员承担。设计人员单方面负责遵守与该等选择有关的所有法律或监管要求。

设计人员同意向 TI 及其代表全额赔偿因其不遵守本通知条款和条件而引起的任何损害、费用、损失和/或责任。
